- Simple Linear Regression JF Chapter 5

Column space

Definition: The column space of a matrix, denoted by $C(\mathbf{A})$ is the vector space spanned by the columns of the matrix, that is,

$$C(\mathbf{A}) = \{\mathbf{x} : \text{ there exists a vector } \mathbf{c} \text{ such that } \mathbf{x} = \mathbf{Ac} \}.$$

This means that if $\mathbf{x} \in C(\mathbf{A})$, we can find coefficients c_i such that

$$\mathbf{x} = \sum_{j} c_j \mathbf{a}^{(j)}$$

where $\mathbf{a}^{(j)} = \mathbf{A}_{\cdot j}$ denotes the jth column of matrix \mathbf{A} .

- The column space of a matrix consists of all vectors formed by multiplying that matrix by any vector.
- The number of basis vectors for $C(\mathbf{A})$ is then the number of linearly independent columns of the matrix \mathbf{A} , and so, $\dim(C(\mathbf{A})) = \operatorname{rank}(\mathbf{A})$.
- The dimension of a space is the number of vectors in its basis.

Example A.2

Let
$$\mathbf{A} = \begin{bmatrix} 1 & 1 & -3 \\ 1 & 2 & -1 \\ 1 & 3 & 1 \\ 1 & 4 & 3 \end{bmatrix}$$
 and $\mathbf{c} = \begin{bmatrix} 5 \\ 4 \\ 3 \end{bmatrix}$. Show that $\mathbf{A}\mathbf{c}$ is a linear combination of columns

Result A.1

$$rank(\mathbf{AB}) \leq min(rank(\mathbf{A}), rank(\mathbf{B})).$$

Result A.2

- (a) If $\mathbf{A} = \mathbf{BC}$, then $C(\mathbf{A}) \subseteq C(\mathbf{B})$.
- (b) If $C(\mathbf{A}) \subseteq C(\mathbf{B})$, there there exists a matrix \mathbf{C} such that $\mathbf{A} = \mathbf{BC}$.

Null space

Definition: The null space of a matrix, denoted by $N(\mathbf{A})$, is $N(\mathbf{A}) = \{\mathbf{y} : \mathbf{A}\mathbf{y} = \mathbf{0}\}.$

Result A.3

If **A** has full-column rank, then $N(\mathbf{A}) = \{\mathbf{0}\}.$

Theorem A.1

Assume $\mathbf{A} \in \mathbb{R}^{m \times n}$, then $\dim(C(\mathbf{A})) = r$ and $\dim(N(\mathbf{A})) = n - r$, where $r = \operatorname{rank}(\mathbf{A})$. See JM Appendix Theorem A.1 for the proof.

Interpretation: "dimension of column space + dimension of null space = # columns" MisInterpretation: Columns space and null space are orthogonal complement to each other. They are of different orders in general! Next result gives the correct statement.

Simple linear regression

Figure 3.1 shows Davis's data on the measured and reported weight in kilograms of 101 women who were engaged in regular exercise.

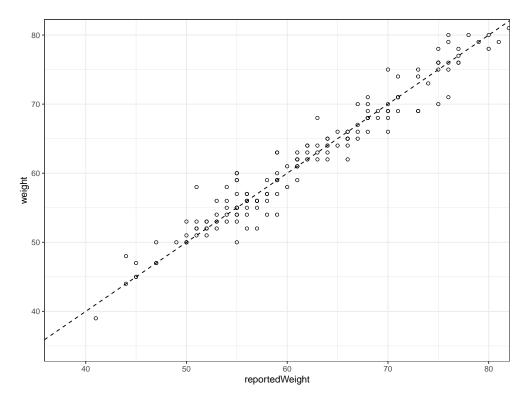

Figure 3.1: Scatterplot of Davis's data on the measured and reported weight of 101 women. The dashed line gives y = x.

It's reasonable to assume that the relationship between measured and reported weight appears to be linear. Denote:

- measured weight by y_i : response variable or dependent variable
- \bullet reported weight by x_i : **predictor variable** or **independent variable**
- intercept: β_0
- slope: β_1
- residual/error term ϵ_i .

Then the simple linear regression model writes:

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i.$$

For given $(\hat{\beta}_0, \hat{\beta}_1)$ values, the *fitted value* or *predicted value* for observation i is:

$$\hat{y}_i = \hat{\beta}_0 + \hat{\beta}_1 x_i.$$

Therefore, the residual is

$$\epsilon_i = y_i - \hat{y}_i$$

Fitting a linear model

Choose the "best" values for β_0, β_1 such that

$$SS[E] = \sum_{1}^{n} \left(y_i - (\hat{\beta}_0 + \hat{\beta}_1 x_i) \right)^2 = \sum_{1}^{n} (y_i - \hat{y}_i)^2 = \sum_{1}^{n} \epsilon_i^2$$

is minimized. These are **least squares** (LS) estimates:

$$\hat{\beta}_{0} = \bar{y} - \hat{\beta}_{1}\bar{x} \hat{\beta}_{1} = \frac{\sum (x_{i} - \bar{x})(y_{i} - \bar{y})}{\sum (x_{i} - \bar{x})^{2}}.$$

Definition: The line satisfying the equation

$$y = \hat{\beta}_0 + \hat{\beta}_1 x$$

is called the linear regression of y on x which is also called the least squares line. For Davis's data, we have

$$n = 101$$

$$\bar{y} = \frac{5780}{101} = 57.228$$

$$\bar{x} = \frac{5731}{101} = 56.743$$

$$\sum (x_i - \bar{x})(y_i - \bar{y}) = 4435.9$$

$$\sum (x_i - \bar{x})^2 = 4539.3,$$

so that

$$\hat{\beta}_1 = \frac{4435.9}{4539.3} = 0.97722$$

$$\hat{\beta}_0 = 57.228 - 0.97722 \times 56.743 = 1.7776$$
